Fault diagnosis

Cooling performance check

Every workshop needs, besides special tools, technical knowledge to do a proffesional job. This can be purchased by special training. This applies particularly to air-conditioning systems. The following instructions can merely serve as guide due to the different systems in use.

 Start the engine. Switch through blower stages 	 Let the system run for a few minutes at max. cooling. Blower must be switched on in middle position. 	
Blower works?	Air outlet temperature at the centre vent 3-8°C.	
Yes No	Yes No	
2.	6.	
- Check the fuse,	Outlet temperature is to warm:	
relays, switches, wiring	- Heater turned off?	
\bullet	- Pollenfilter o.k. ?	
•	- Check temperature switch/-sensor,	
3.	- Check thermostat (if available)	
Switch cooling to max.	- Ventilation damper, heater valves,	
	condenser ventilation must be checked	
Magnetic coil activated ?	*	
	7. Proof low-(LP) and high pressure (HP) at 2000 – 2500 rpm :	
Yes No	LP: 0,5 – 3,0 bar HP: 6,0 – 25,0 bar	
4.	with load controlled compressors:	
 Check wiring/electr. connections, current supply (+/-) 	LP: ~ 2 bar, constant	
- Temperature switch-/sensor,	Yes No	
- Check pressure switch		
 Check refrigerant charge 	see table for pressure relationships	
go to 5.	Air conditioning is ok.	

Technical Information

It is very important to correctly interpret the pressure gauge reading. Some typical examples:

Air conditioning with expansion valve					
Low pressure	High pressure	Outlet temperature on centre nozzle	Possible causes		
high	high	higher, up to ambient temperature	overheated engine, foulted condenser, condenser fault- wrong direction of rotation, overfilled system		
normal up to low at times	high, at times	higher perhaps fluctuating	sticked expansion valve, at times closed		
normal	high	slight higher	aged dryer, foulted condenser		
high	normal up to high	higher, depending on contraction	contracted pipe, compressor – to expansion valve		
normal	normal	higher	overcharged with refrigerant oil		
normal, but irregular	normal, but irregular	higher	moisture in the system, faulty expansion valve		
fluctuating	fluctuating	fluctuating	faulty expansion valve or compressor		
normal up to low	normal up to low	higher	foulted evaporator, system underfilled with refrigerant		
high	low	higher, almost ambient temperature	sticked expension valve (opened), faulty compressor		
low	low	higher, up to ambient temperature	system underfilled with refrigerant		
same low and high pressure	same low and high pressure	ambient temperature	system underfilled, faulty compressor or electrical system		

Air-conditioning with orifice tube

high	high	higher, up to ambient temperature	overheated engine, foulted condenser, condenser fault- wrong direction of rotation, overfilled system
normal up to high	high	higher	overfilled system, foulted condenser
normal	normal up to high	fluctuating	moisture in the system, orifice tube blocked at times
high	normal	higher	faulty orifice tube (cross-cut)
normal	normal	higher	system overcharged with oil
normal up to low	normal up to low	higher	system underfilled with refrigerant
same low and high	same low and high	ambient temperature	system underfilled, faulty
pressure	pressure		compressor or electrical system

Ambient temp= surrounding environment temperature. Tests should not be carried out in extreme cold or warm environmental conditions.
